**Subject: Geotechnical Investigation of the IRM Area
Ascon Landfill Site
Huntington Beach, California**

Dear Ms. Zeier:

GENERAL

This letter report documents the results of a geotechnical investigation performed during the course of the Interim Removal Measure (IRM) at the Ascon Landfill Site (Site) in Huntington Beach, California. The extent of the investigation was limited to the area within the footprints of Lagoons 1, 2, and 3. The investigation consisted of a review and interpretation of relevant Site information, drilling, *in-situ* testing, recovery of representative soil samples, and geotechnical laboratory testing of representative soil samples. Detailed background information, including borehole logs, logs of *in-situ* testing, and laboratory testing results, are included in the appendices of this report.

The results of our investigation are presented in the form of interpreted representative soil profiles and tabulated material properties. This information, along with other relevant information from previous investigations at the Site, is intended for future design evaluations at the Site.

PROJECT BACKGROUND

The Site is located at 21641 Magnolia Street in Huntington Beach, California. The approximate location of the Site is shown in Figure 1. An approximate layout of the Site, with approximate property boundary limits and limits of Lagoons 1 through 5 is shown in Figure 2.

The IRM activities focused on removal of tarry wastes from the footprints of Lagoons 1 and 2 to enable this geotechnical program, and the southern portion of Lagoon 3 in order to reduce the load on the berm between Lagoons 2 and 3 and thereby result in greater berm stability and safety between completion of the IRM and implementation of the final remedy at the Site.

Upon completion of tarry material removal in the three lagoons, an access ramp for Lagoons 1 and 2 and a temporary access ramp ('causeway') for Lagoon 3 were constructed and used to allow for drilling rig access. The approximate location of the access ramps (i.e., south end of Lagoon 1-2 and south-central area of Lagoon 3) are shown in Figure 3.

RELEVANT BACKGROUND INFORMATION

There is no relevant background geotechnical information available within the perimeters of the lagoons, as previous access to these areas was impeded by the presence of tarry wastes in Lagoons 1, 2, and 3.

Background hydrogeological information (i.e., contours interpolated between measurements taken at onsite monitoring wells in September 2010) is shown in Figure 3. It should be noted that these elevations were interpreted from groundwater elevations in wells located away from the lagoons and are, therefore, approximate.

Background topographical information (i.e., the approximate topography of the Site at the completion of the IRM) is shown in Figure 3.

GEOTECHNICAL INVESTIGATION

General

The current Site investigation was performed in accordance with the Interim Removal Measure Workplan of 18 May 2010, and it's Addendum for this Geotechnical Investigation of 23 December 2010. The Addendum to the Workplan is reproduced as Appendix A.

Drilling, Sampling, and *In-Situ* Testing

The drilling, *in-situ* testing, and sampling programs were completed in February 2011. Two boreholes were advanced in each of the three lagoons within the IRM area.

Boreholes within Lagoons 1 and 2 were advanced upon removal of the majority of tarry wastes. As the tarry wastes were not completely removed from the southwestern portion of Lagoon 3, drilling was conducted from a temporary access road that was placed within the tarry wastes prior to partial removal.

Boreholes advanced during this drilling program are labeled B-1 through B-6. The approximate locations of these boreholes are shown in plan view in Figure 3 and further in Cross Sections A-A' through C-C' in Figures 4 through 6, respectively. Also indicated in Figures 4 through 6 are the soil sampling intervals, the Standard Penetration Test (SPT) blow counts (un-corrected blow count values), and soil classification in accordance with the Unified Soil Classification System (USCS). The interpreted borehole logs are enclosed in Appendix B. We note that information in Figures 4 through 6 includes soil classification corrections based upon the geotechnical laboratory testing results.

In order to observe groundwater levels near borings B-1 through B-4, hand auger holes were advanced to approximately 5 feet below ground surface (bgs). Each hand auger hole was advanced before the start of drilling near its corresponding borehole and remained open for several hours until completion of the corresponding borehole. Groundwater was observed in hand auger holes near Boreholes B-2 and B-4 (i.e., where hand auger holes penetrated through the fine-grained layer into the underlying relatively permeable silty sand). Hand auger holes near borings B-1 and B-3 did not penetrate through the fine-grained layer and therefore did not encounter groundwater. Groundwater elevations observed in hand auger holes are indicated in Figures 3 through 5. These observed groundwater elevations are within the range of levels previously recorded for Site groundwater monitoring wells.

Geotechnical Laboratory Testing

Geotechnical laboratory testing was performed on representative soil samples recovered from the boreholes. The representative soil samples were recovered either by pushing thin-walled Shelby™ tubes or by driving the SPT or California Modified samplers, as indicated in Figures 4 through 6.

The geotechnical laboratory testing program included soil classification (ASTM D2487), moisture content and density testing (ASTM D2216 & D2937), and saturated hydraulic conductivity testing (ASTM D5084). Modified Proctor compaction testing (ASTM D1557) was also conducted on three representative soil samples. The

results of the geotechnical laboratory testing are enclosed in Appendix C. Interpreted test results are shown in Figures 7 through 11 and are commented upon in the section below.

INTERPRETATION OF SITE CONDITIONS

General

The complete information collected during this geotechnical investigation program is shown in Figures 4 through 12. This includes sampling locations, sample types, SPT blow counts (uncorrected), the interpreted results of groundwater elevation measurements, stratification, and soil classification based upon the results of visual observation during drilling and geotechnical laboratory testing. The information shown in Figures 4 through 6 indicates that soil profiles within the lagoon area are horizontally layered and generally dominated by two distinct layers: (i) a relatively low-hydraulic conductivity fine-grained/cohesive soil layer that gradually transitions into (ii) relatively high hydraulic conductivity, medium dense layer of mostly cohesionless soils.

Fill is present (i.e., was placed) within a limited area of Lagoons 1 and 2 to provide desired grade for surface water control, and as the access road/causeway material in Lagoon 3. Tarry wastes left in place within the footprint of Lagoon 3 and below the causeway are also shown in Figures 4 and 6.

Characterization of Site Soils

The low-hydraulic conductivity fine-grained/cohesive soil layer (fine-grained layer) is composed of silt (MH) and silty clay (CH). This layer gradually transitions into a clayey sand (SC) layer and further into a silty sand (SM) layer. The thickness of the fine-grained layer varies from 0 to 5 ft. Information presented in Figure 7 indicates that this fine-grained material is generally of high plasticity (representative Plasticity Index, PI = 17 % to 32 %). Figure 9 indicates that this fine-grained material is normally consolidated, and therefore highly compressible (representative strain-based Compression Index, C_c = 12 to 15). Consistent with results of consolidation testing, the results of triaxial testing (Figure 10) show that this layer is relatively weak, as characterized by drained friction angle of 22° to 33° and undrained shear strength of approximately 4 psi. Figure 11 shows that saturated hydraulic conductivity of this fine-grained material is relatively low (less than 10^{-5} cm/s at confining stress of 2.5 psi, which corresponds to present *in-situ* conditions, and less than 10^{-6} cm/s at confining

stress of 20 psi, which corresponds to estimated in-situ conditions at the same elevation at the time of Site closure, assuming the construction of a cap and additional backfill to design grades.

The relatively high hydraulic conductivity, medium dense layer (coarse-grained layer) of mostly cohesionless soils is composed of silty sand (SM), well-graded sand (SW), and clayey sand (SC). At depths exceeding approximately 30 ft, inter-bedded, relatively thin (up to 5 ft) layers of silty clay (CL) and silt (ML) were found. In general, the coarse-grained layer is characterized by a relatively high percentage of fines (particles passing standard US sieve No. 200, see Figure 8). The results of in-hole SPT sounding indicate that the density of this layer is typically medium dense (SPT N = 20 to 30 blows per foot) but varies from loose (SPT N = 9 blows per foot) to dense (SPT N = 55 blows per foot).

Fill that was placed within limited areas of Lagoons 1 and 2 and as the causeway material in Lagoon 3 consists of onsite available materials, including silty sand and silty clay. Compaction characteristics of these materials are presented in Appendix C.

Tarry wastes left in place within the footprint of Lagoon 3 and below the causeway were not tested as a part of the activities documented in this report.

CLOSURE

This Report was prepared by Mr. Alan Witthoeft, E.I.T., and Dr. Neven Matasovic, P.E., G.E., of Geosyntec. The report was peer reviewed by Mr. Ken Fredianelli, also of Geosyntec. Should you have any questions or require additional information regarding this memorandum, please feel free to contact Neven Matasovic at 714-465-1244.

Sincerely,

Alan Witthoeft, E.I.T.
Senior Staff Engineer

Neven Matasovic, Ph.D., P.E., G.E.

Addendum to Interim Removal Measure Workplan

Dear Mr. Sayed:

Enclosed please find two copies of the Addendum to the Interim Removal Measure Workplan for the Ascon Landfill Site located in Huntington Beach, California. We plan to begin the geotechnical sampling/work outlined in this Addendum during the first week in January 2011, contingent on weather and field conditions.

Please feel free to contact me if you have any questions at (714) 863-0017 or tzeier@projectnavigator.com.

Sincerely,

A handwritten signature in blue ink that reads "Tamara Zeier".

Introduction

This Addendum to the Ascon Landfill Site Interim Removal Measure Workplan (Addendum) has been prepared by Geosyntec Consultants (Geosyntec) and Project Navigator, Ltd. (PNL) on behalf of the Ascon Landfill Site Responsible Parties (RPs). The Ascon Landfill Site (Site) is located in Huntington Beach, California, with the street address 21641 Magnolia Street. The purpose of this Addendum is to outline the proposed geotechnical investigation conceptually described in the DTSC-approved Interim Removal Measure Workplan (Workplan). In addition, the Addendum describes certain changes from the approved Workplan. These changes were made in consideration of: (i) expanded scope of work, namely, excavation in Lagoon 3; (ii) observed conditions in the field; and (iii) minimizing the possibility of contaminating the groundwater below the Site resulting from the drilling method proposed in the approved Workplan. For convenience, relevant information from the Workplan is reproduced here.

Proposed Scope of Geotechnical Investigation

The proposed geotechnical investigation will commence after preparation of firm working surfaces (i.e., level surfaces able to bear the weight of a drill rig) in Lagoons 1, 2, and 3. The material underlying the former lagoon material will be cored and sampled via mud rotary drilling techniques. Mud rotary drilling is proposed here (instead of hollow-stem auger drilling, as proposed in the Workplan) because mud rotary is more likely than hollow-stem auger to: (i) prevent potentially impacted perched groundwater from flowing downward through the borehole and (ii) allow for effective grouting of the borehole upon completion of drilling.

A mud rotary drill rig will be used to drill one borehole in Lagoon 1, one borehole in Lagoon 2, and one borehole in Lagoon 3, for a total of three boreholes. Additional boreholes (e.g., additional borehole per lagoon) may be drilled if the RPs decide this would help meet the project objectives or if field conditions warrant additional data (e.g., due to significant visual differences in the subsurface material). DTSC will be informed of any additional borings. The approximate locations of the proposed boreholes are indicated in Figure 1. Field conditions may warrant the relocation of the boreholes. DTSC will be notified of the actual drilling locations and number of boreholes after confirmed in the field. It is noted that the Workplan proposes only two boreholes (one in Lagoon 1 and one in Lagoon 2). The increase in number of boreholes is proposed in light of the expanded scope of work, which was not anticipated by the Workplan, and the desire to gather additional geotechnical information that will be useful in preliminary remedy planning and design.

The boreholes will have an approximate diameter of 3.75 in. and will be advanced to a depth of approximately 50 ft below existing ground surface (i.e., existing after excavation of lagoon

material during the IRM). Samples of the clayey material near the bottoms of the lagoons will be collected using a California modified sampler and a Shelby™ tube sampler. Samples of the material underlying the clayey material will be collected using a standard penetration test (SPT) sampler. After completion of drilling and sampling, each borehole will be back-filled with cement-bentonite grout tremied into place from total depth to surface and will be capped with concrete.

Selected samples are planned to be tested for the following geotechnical properties:

- Grain size distribution by ASTM D-422;
- Atterberg Limits (Plasticity Index, Liquid Limit) by ASTM D-4318;
- Compaction characteristics by ASTM D-1557;
- Moisture content and unit weight by ASTM D-2216, D-2937, and D-4643;
- Consolidation by ASTM D-2435;
- Hydraulic conductivity by ASTM D-5084; and
- Consolidated Undrained Shear by ASTM D-4767.

Changes to the proposed testing regimen from that proposed in the Workplan are outlined in Table 1 below. The results of the testing program proposed here will be used to provide geotechnical input for the design of the interim configuration of the Lagoon bottoms. The Workplan does not address the issue of design of interim configuration. DTSC will be notified of potential changes to the testing regimen.

As stated above, the proposed scope of the geotechnical investigation as outlined in this Addendum differs from that described in the Workplan. Table 1 below compares material elements of the geotechnical investigation methods between the Workplan and this Addendum.

Deliverables

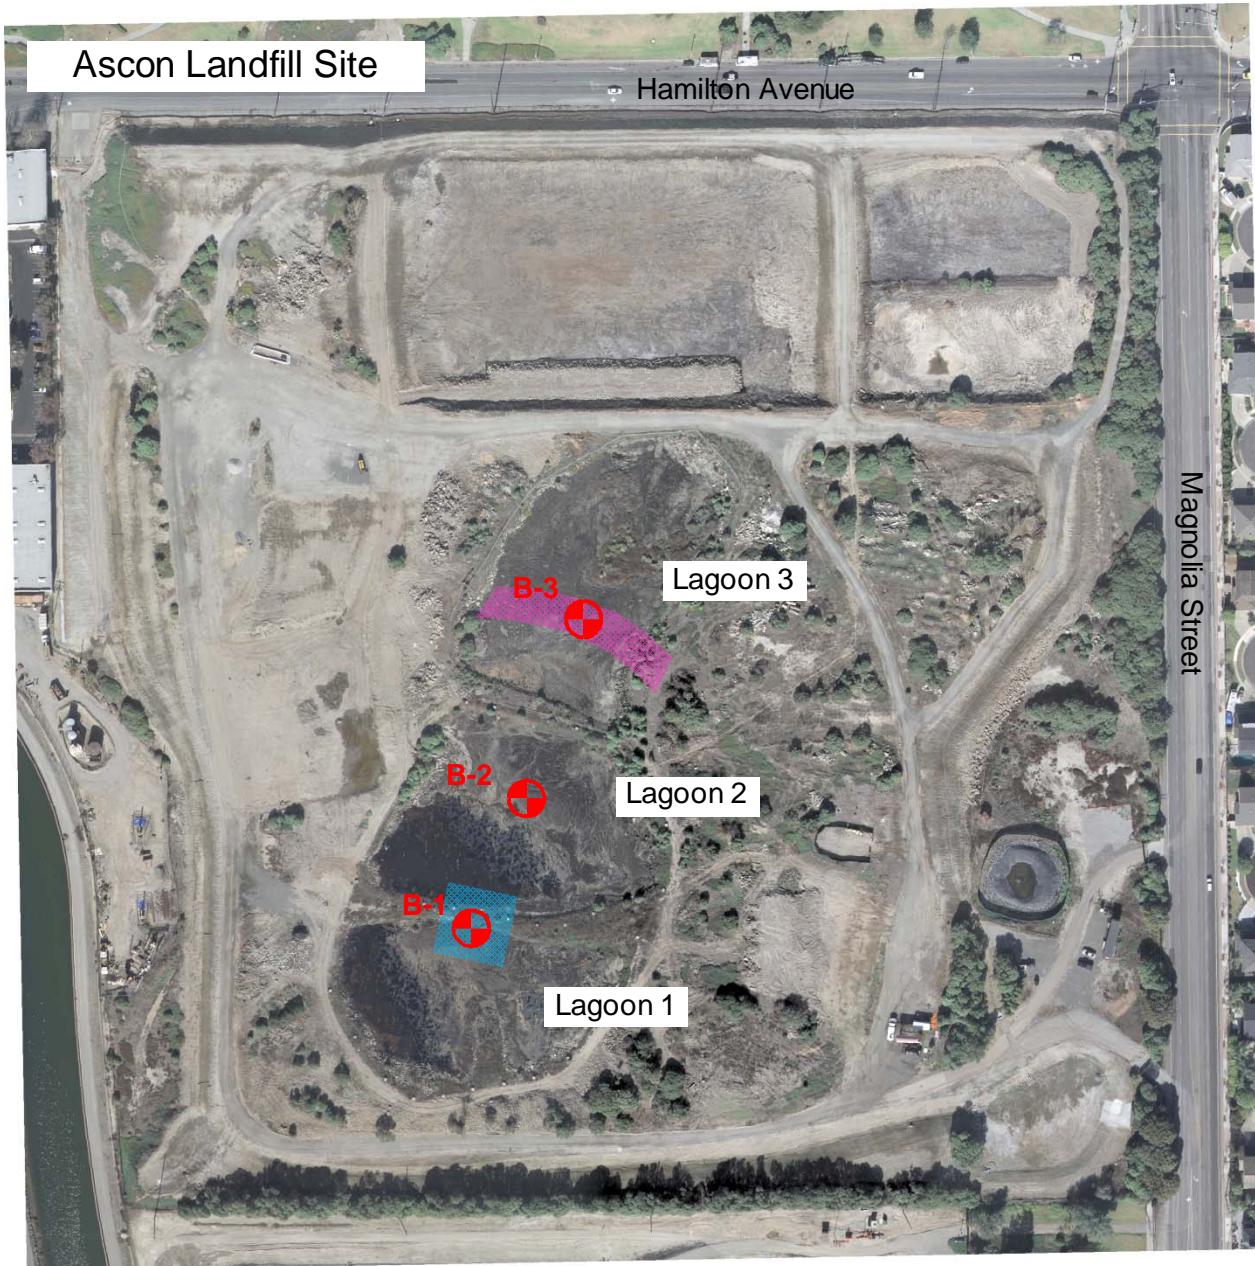

A summary letter report will be prepared and submitted to DTSC describing the findings from the work outlined in this Addendum and geotechnical recommendations. This report will be prepared under supervision of and signed by a California-Registered Geotechnical Engineer.

Health and Safety

The RPs and their contractors understand the hazards associated with working on the Site and with performing geotechnical drilling. The contractors performing the work will both implement task-specific measures and adhere to applicable Site-specific and applicable company-wide health and safety policies. Task-specific measures will include:

- Preparation of a Job Safety Analysis (JSA), outlining potential hazards and corresponding mitigation strategies;
- Convening of a daily tailgate safety meeting informing Site personnel of relevant health and safety issues, response measures, etc.;
- Real-time air monitoring in the breathing zone using a 4-gas meter; and
- Access to mitigation measures (e.g., respirators, etc.).

Site-specific health and safety measures are outlined in the Interim Removal Measure Health and Safety Plan attached to the DTSC-approved Workplan as Appendix B.

Project No: 475
Site Sample ID: B-6-4
Lab Sample No: 11B324E

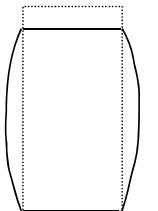

ASTM D 4767

**CONSOLIDATED-UNDRAINED (CU) TRIAXIAL TEST
WITH PORE PRESSURE MEASUREMENTS**

Figure 1

Test Specimen No.	Maximum Strength				
	$\sigma'_1 - \sigma'_3$ (psi)	σ'_1 (psi)	σ'_3 (psi)	u (psi)	ϵ_a (%)
1	13.1	17.3	4.2	63.3	15.2
2	16.9	21.6	4.7	70.3	14.9
3	24.8	36.2	11.4	78.6	15.2

Test Specimen No.	Strength at App. 15% Axial Strain				
	$\sigma'_1 - \sigma'_3$ (psi)	σ'_1 (psi)	σ'_3 (psi)	u (psi)	ϵ_a (%)
1	13.1	17.3	4.2	63.3	15.2
2	16.9	21.6	4.7	70.3	14.9
3	24.8	36.2	11.4	78.6	15.2

Notes:

σ'_c = Consolidation pressure, (psi)
 σ'_1 = Effective axial stress, (psi)
u = Pore pressure,(psi)

u_i = Initial pore pressure,(psi)
 σ'_3 = Effective radial stress (confining pressure), (psi)
 ϵ_a = Axial strain, (%)

$\sigma'_1 - \sigma'_3$ = Deviator stress, (psi)

FLEXIBLE WALL PERMEABILITY TEST⁽¹⁾

ASTM D 5084 *

Project Name:	Ascon IRM Geotechnical Investigation
Project Number:	475
Client Name:	Geosyntec Consultants
Site Sample ID:	B-2-2
Lab Sample Number:	11B321E
Material Type:	NA
Specified Value (cm/sec):	NA
Date Test Started:	2/18/2011

Specimen No.	Test Specimen Initial Condition					Test Conditions					Hydraulic Conductivity (cm/s)
	Spec. Prep. ⁽²⁾ (-)	Spec. Length (cm)	Spec. Diameter (cm)	Dry Unit Weight (pcf)	Moisture Content (%)	Cell Press. (psi)	Back Press. (psi)	Consolid. Press. (psi)	Permeant Liquid ⁽³⁾ (-)	Average Gradient (-)	
1	ST	5.74	7.23	99.7	24.0	62.5	60.0	2.5	DTW	15	2.6E-6
						80.0		20.0		15	2.0E-7

Notes:

1. Method C, "Falling-Head, Increasing-Tailwater" test procedures were followed during the testing.
2. Specimen preparation: ST = Shelby Tube, R = Remolded, B = Block Sample.
3. Type of permeant liquid: DTW = Deaired Tap Water, DDI = Deaired Deionized Water

* Deviations:

Laboratory temperature at 22±3 °C.

Test specimen final conditions are not presented.
