**Geotechnical Interpretation
and
Summary by Parsons**

1.0 GEOTECHNICAL ANALYSIS

1.1 Geotechnical Analysis Results

Twenty-five (25) geoprosbes and ten (10) piezometers were installed within the Site boundaries, as shown in **Figure 2-1**. In addition to collecting geologic and chemical sampling information, geotechnical samples were collected to evaluate the physical condition of fill and waste at the Site.

Soil samples were obtained from each piezometer location using a 2 inch diameter "California" split spoon sampler. Split spoon samples were obtained continuously at some locations and on 5 foot spacing intervals from the remaining locations. Standard Penetration Tests (SPT) were conducted at each piezometer sample interval in accordance with ASTM D1586 using a 140-pound hammer falling freely 30 inches to drive the sampler. Soil samples were obtained from each geoprobe location using a 1 ½ inch diameter, four-foot long acetate lined rod. Soil borings were monitored, and recovered samples were visually classified using the Unified Soil Classification System (USCS) (ASTM D2488). Soil boring logs are presented in **Appendix A**.

The program involved collection of undisturbed soil samples using 3 inch diameter, 30 inch long thin-walled Shelby tubes. However, due to the amount of concrete, debris and loose material encountered in the holes, recoverable samples could not be obtained with Shelby tubes. Therefore, samples were collected with split spoon samplers to ensure that a significant amount of recoverable material was obtained in the samplers.

1.1.1 Geotechnical Laboratory Testing Program

Ninyo & Moore located in Irvine, California performed geotechnical laboratory testing. The following geotechnical laboratory tests were performed on selected soil samples:

- Particle Size Distribution (ASTM D 422), including sieve and hydrometer analysis
- Atterberg limits (ASTM D 4318)
- In-place moisture content and density (ASTM D 2216 and D 2937)
- Hydraulic conductivity (ASTM D 5084)
- Maximum dry density and optimum moisture content (ASTM D 1557)
- Unconfined compression (ASTM D 2166)
- Consolidated-undrained triaxial compression (CIU) (ASTM D 4767)

The index tests (sieve, hydrometer, and Atterberg Limits) were performed on selected samples for laboratory soil classification and to verify visual classifications made in the field. Hydraulic conductivity, density, and compression tests were performed on selected samples to estimate the permeability values, bearing capacity, and effective strength parameters. The geotechnical test results for each stratum are presented and summarized below.

1.1.2 Interpretation of Results

1.1.2.1 Subsurface Soil Conditions

Based upon the results of the field investigations, three soil strata (designated Stratum I, II, and III) of geologic interest have been identified. The three strata are differentiated by their waste characterization and composition and are labeled as follows:

- Stratum I Fill: Soil
- Stratum II Fill: Waste & Impacted Material
- Stratum III Native Material

A description of the three strata and their engineering properties are provided below. Based on the results of the subsurface investigation, five subsurface cross-sections were developed and are presented in **Figures 4-4 through 4-8**.

1.1.2.1.1 Stratum I – Fill: Soil

Stratum I consists of heterogeneous fill material composed of mainly "silty sand" and "sandy silt". In several borings there are varying amounts of gravel, clay and construction debris (such as concrete, asphalt, and brick).

Stratum I was encountered in all piezometers and geoprobe locations with the thickness ranging from 2 feet (GP-5) in the southwestern portion of the Site to 20 feet (P-6 and GP-18) in the central portion of the Site. A summary of the subsurface conditions encountered is presented in **Table E-1**. The Standard Penetration Test (SPT) value in Stratum I ranged from 10 (P-5) to 81 (P-6) blows per foot.

Geotechnical laboratory testing was conducted on numerous samples obtained from Stratum I. The results are presented in **Appendix D**. Based on the laboratory tests, the USCS classification for Stratum I is generally a silty sand (SM) and clayey sand (SC). Sieve analysis tests (including hydrometer) were performed on ten Stratum I samples and the fines content (i.e., percentage

passing the number 200 sieve) ranged from 20 (P6-2) to 53 percent (P10-1.5), with the exception of 8 percent at soil boring P5-2. The results of the sieve analysis test generally indicate that Stratum I is a "coarse-grain" material. Atterberg limits were performed on ten Stratum I samples and were determined to have a plasticity index ranging from 1 (P5-2) to 12 percent (P3-5.5 and P4-1.5) and a liquid limit ranging from 17 (P5-2) to 33 percent (P4-1.5). These plasticity values generally indicate that the soil is a non to low plasticity soil.

Based on in-place tests performed at 19 locations in Stratum I, the density varied from 75.7 pcf (P-7) to 112.9 pcf (P-6) and the water content varied from 2.0 (P-5) to 39.2 percent (P-7). A laboratory compaction test was performed on one sample from Stratum I and the maximum dry density was estimated to be 130.5 pcf at an optimum water content of 7.5 percent. It can be noted that all in-place density values obtained were below the maximum dry density value at the optimum water content.

The vertical permeability of Stratum I was tested in 10 locations and ranged from 6.29×10^{-7} cm/sec (P3-6) to 9.9×10^{-5} cm/sec (P10-2). This generally can be considered a moderate to low permeability material. Based on unconfined compression tests that were performed on seven Stratum I samples, the shear strength was estimated to vary from 430 (P-4) to 1670 pounds per square foot (psf) (P-8).

1.1.2.1.2 Stratum II – Fill: Waste & Impacted Material

Stratum II is also considered a fill layer generally consisting of mud, oily soil waste and other oil or hydrocarbon impacted material. More specifically, the waste and impacted material consists of soil (varying from a clayey silt to poorly graded sand with gravel) and material characterized in the field as "drilling mud." Both materials encountered were saturated with oil and hydrocarbon staining and odor was observed in all the investigation locations. In several borings, varying amounts of construction debris was encountered. The material described as drilling mud generally consists of a dewatered bentonite-based slurry that exhibits the behavior of a low to high plasticity clay and is designated as Stratum II-M (for mud).

Stratum II was generally encountered throughout the Site in all ten of the piezometers and all 25 of the geoprosbes. When Stratum II was encountered, Stratum II-M was also encountered, except at locations P-10, GP-4 through GP-6, GP-12 through GP-15, GP-18, GP-21, and GP-22. The thickness of Stratum II ranged from 3 feet (GP-21) in the southwestern portion of the Site to 26.5 feet (GP-2) in the northwest portion of the Site. A summary of the subsurface conditions encountered is presented in **Table E-1**.

The Standard Penetration Test (SPT) value in Stratum II ranged from 2 (P-3) to 35 blows per foot (P-6, P-9, P-10), with the exception of SPT values in the 50s in borings P-4 and P-10. The Stratum II SPT values were generally less than the Stratum I SPT values.

Geotechnical laboratory testing was conducted on numerous samples obtained from Stratum II. The results are presented in **Appendix D**. Based on laboratory tests, the USCS classification for Stratum II generally ranged from a sandy clay (SC) to a fat clay or high plasticity clay (CH).

Sieve analysis tests (including hydrometer) were performed on nine Stratum II samples and the fines content ranged from 36 (P-9) to 100 percent (P-6). The results of the sieve analysis test general indicate that Stratum II is a “fine-grain” material. Atterberg limits were performed on nine Stratum II samples and were determined to have a plasticity index ranging from 14 (P-4) to 56 percent (P-2) and a liquid limit ranging from 35 (P-4 and P-8) to 79 percent (P-2). These plasticity values generally indicate that the soil is a moderate to high plasticity soil. The testing indicates that Stratum II and Stratum II-M generally do not differ in engineering properties.

Based on in place tests performed at 19 locations in Stratum II, the density varied from 41.3 pcf (with a water content of 77 percent at P-6) to 103.4 pcf (P-4) and the water content varied from 5.5 percent (P-1) to 101.8 percent (with a density of 42.1 pcf at P-9). A laboratory compaction test was performed on one sample from Stratum II and the maximum dry density was estimated to be 103.0 pcf at an optimum water content of 13.0 percent.

The vertical permeability of Stratum II was tested in eight locations and ranged from 1.54×10^{-7} cm/sec (P-4) to 1.27×10^{-8} cm/sec (P-1). This generally can be considered a low permeability material. Based on unconfined compression tests that were performed on 10 Stratum II samples, the estimated shear strength varied from 250 psf (P-6) to 750 psf (P-4). Based on these results, the estimated shear strength of Stratum II is generally lower than that of Stratum I.

Lastly, isotropically consolidated undrained triaxial compression (CIU) tests were performed on four Stratum II samples. Based on these tests, the effective shear strength of three samples (P-1, P-2, and P-5) was determined to be 500, 500, and 300 psf with an effective friction angle of 19, 8, and 8 degrees, respectively. The estimated shear stress obtained from the unconfined compression tests were in general agreement of the effective shear stress obtained from the CIU tests.

Both Stratum I and Stratum II are considered fill and are heterogeneous in nature. In addition, it is assumed that the fill materials were placed in an uncontrolled manner and were not compacted/tested in an engineered manner. Based on the coarse grained nature of the soil, the SPT values, and the laboratory data, it appears that Stratum I could support short-term loading (such as construction equipment). However, due to the cohesive nature of the soil and the relatively low effective shear stress and friction angle of Stratum II, it is recommended that additional evaluation (such as bearing capacity and differential settlement analyses) be conducted if short-term loading is planned to occur directly on Stratum II. In addition, it is recommended that additional evaluation be performed (including evaluating excavating the fill and replacing it with compacted structural fill) if long-term loading at the Site is considered.

1.1.2.1.3 Stratum III – Native Material

Stratum III consists of native material and is composed of silt, varying in sand and clay content, grading with depth to sand, varying in silt content. In several borings, varying amounts of seashells were observed. Hydrocarbon staining or odor was not observed. Organic silt was observed in piezometer P-5. The silt was visually classified as an inorganic silt, very fine sand, silty or clayey fine sand (ML) or inorganic clay of low to medium plasticity, gravelly clay, sandy clay, silty clay, lean clay (CL), and the sand was visually classified as a poorly graded sand and gravelly sand (SP) or silty sand (SM).

Stratum III was encountered in 9 of the 10 piezometers and 14 of the 25 geopros. The thickness of Stratum III was greater than 10 feet at locations P-1, P-4, P-5, P-6, GP-12, and GP21. A summary of the subsurface conditions encountered is presented in **Table E-1**. The Standard Penetration Test (SPT) values in Stratum III ranged from 8 blows per foot (P-4) to less than 40 blows per foot, with the exception of P-1 (75) and P-6 (58).

Geotechnical laboratory testing was not conducted on any samples obtained from Stratum III.

Table E-1
Summary of Subsurface Conditions

Notes: Used 8-inch O.D. auger for pilot boring for lithologic sampling. Reamed pilot boring with 12-inch O.D. augers to set 6-inch diameter PVC casing. Set bottom of well at 36 feet. Set well screen (0.020-inch) from 26 to 36 feet. Used 7-100 lb bags of #2½ Sand from 25 to 36 feet bgs; 2-50 lb bags of bentonite chips (hydrated) from 22 to 25 feet bgs; 80 gallons of bentonite slurry from surface to 23 feet bgs. PVC stickup is 2.20 feet tall; with PVC slip cap.

					DESCRIPTION	
Oppm	Fine & Coarse Fill	16:19	GP		Grass Ground Surface Commenced drilling GP-21 at 15:53 on 9/12/02 Pale Brown (10YR 6/3); SILTY SAND (SM); Surface to 2 feet; fine to medium grained sand (85%); silt (15%); loose, no HC odor. Dark Grayish Brown (10YR 4/2); POORLY GRADED SAND WITH GRAVEL (GP); 2 to 3 feet Very Dark Grayish Brown (10YR 3/2); SILT (ML); 3 to 4½ feet; no HC odor.	
Oppm	Impact Soil Waste	17:08	Debris		Dark Grayish Brown (10YR 4/2); POORLY GRADED SAND WITH GRAVEL (GP); 4½ to 11 feet; fine to medium grained sand (60%); gravel (40%); with fragments of asphalt debris; no HC staining; slight HC odor. Sample I.D.; Ascon-GP21-12; Sample collected in 2-4 oz. jars; 1-acetate sleeve and 3-Encore containers for analysis for VOCs, SVOCs and TPH by EPA Methods 8260B, 8270C and 8015M, respectively. Black (10YR 2/1); ASPHALT DEBRIS; 11 to 12 feet; HC odor.	
Oppm		17:20	ML		Very Dark Grayish Brown (10YR 3/2); POORLY GRADED SAND WITH GRAVEL (GP); 12 to 14 feet; fine to medium grained sand (60%); gravel (40%); no HC staining; slight HC odor. Dark Grayish Brown (10YR 4/2); SILT (ML); 14 to 19½ feet; low plasticity; firm; no HC staining; no HC odor.	
Oppm	Native	07:25	SP-SM		Gray (10YR 4/1); POORLY GRADED SAND WITH SILT (SP-SM); 19½ to 28 feet; fine grained sand (80%); silt (20%); abundant sea shells; wet; no HC staining; no HC odor.	
Oppm					Total depth of well at 26 feet bgs	
Oppm					Pilot boring terminates at 28 feet bgs	
					<u>Notes:</u>	
					(1) Used 1½-inch diameter, 4-foot long acetate lined rod.	▽ Groundwater at time of drilling
					(2) HC - Hydrocarbon	▽ Groundwater measured after well completed.
					(3) Oil waste consists of black free-phase hydrocarbons.	○ Water Seepage
					(4) Commenced drilling GP-21 at 15:53 on 9/12/02.	
					<u>Notes:</u> Used 1½-inch O.D. direct-push rod for pilot boring for lithologic sampling. Reamed pilot boring with 2½-inch O.D. direct-push rods to set 1-inch diameter casing. Set bottom of well at 26 feet bgs. Set well screen (0.020-inch) from 16 to 26 feet bgs. Used 1-100 lb bag of #2½ Sand from 15 to 28 feet bgs; 1-50 lb bag of bentonite chips (hydrated with 1 gallons of water) from 12 to 15 feet bgs; 10 gallons of bentonite grout from surface to 12 feet bgs. PVC stick up is 2.10 feet tall; with PVC slip cap.

Subject: Laboratory Testing Results
Ascon Landfill
Huntington Beach, California

Dear Mr. Russo:

Presented herein are the laboratory testing results performed on soil samples obtained by your firm from the Ascon Landfill that is located at 21641 Magnolia Street, Huntington Beach, California. The results of our laboratory testing are presented in the tables and figures in Appendix A. Copies of the Analysis Request & Chain of Custody Records are presented in Appendix B.

We appreciate the opportunity to be of service on this project. Should you have any questions or comments relative to the information included, please contact the undersigned at your convenience.

Sincerely,
NINNYO & MOORE

APPENDIX A

LABORATORY TESTING

Classification

Soils were classified in accordance with the Unified Soil Classification System (USCS) in general accordance with ASTM D 2488-93. Soil classifications are indicated on the laboratory test results.

In-Place Moisture and Density Tests

The moisture content of samples obtained from the exploratory excavations was evaluated in accordance with ASTM D 2216-98 and ASTM D2937-00. The test results are shown on Figures A-1 through A-3.

Gradation and Hydrometer Analysis

Gradation analysis tests were performed on soil samples in general accordance with ASTM D 422-95. The grain-size distribution curves are shown on Figures A-4 through A-22. These test results were utilized in evaluating the soil classifications in accordance with the Unified Soil Classification System.

Atterberg Limits

Tests were performed on soil samples to evaluate the liquid limit, plastic limit, and plasticity index in general accordance with ASTM D 4318-00. These test results were utilized to evaluate the soil classification in accordance with the Unified Soil Classification System. The test results and classifications are shown on Figures A-23 through A-25.

Maximum Dry Density and Optimum Moisture Content Tests

The maximum dry density and optimum moisture content of selected representative soil samples were evaluated in general accordance with ASTM D 1557-00. The results of these tests are summarized on Figures A-26 and A-27.

Hydraulic Conductivity Tests

Hydraulic conductivity testing using a flexible wall permeameter was performed on undisturbed soil samples in general accordance with ASTM D 5084-00. The results of these tests are presented on Figure A-28.

Consolidated Undrained Triaxial Compression Tests

Consolidated undrained triaxial compression tests were performed on selected undisturbed samples in general accordance with ASTM D 4767-95. Cylindrical specimens with a length-to-diameter ratio of 2:1 were saturated by back pressures until a degree of saturation of 95 percent or higher was achieved. Then the specimen was consolidated isotropically under a predetermined confining pressure. After completion of consolidation, the sample was sheared undrained under compression at a constant rate of axial deformation either with or without measurements of pore pressure. The test results are shown on Figures A-29 through A-32.

Unconfined Compression Tests

Unconfined compression tests were performed on remolded and undisturbed samples in general accordance with ASTM D 2166-00. The test results are shown on Figures A-33 through A-49.
